(Received 14 January 2008; revised manuscript received 12 June 2008; published 5 August 2008)

We present two families of analytical solutions of the one-dimensional nonlinear Schrödinger equation, which describe the dynamics of bright and dark solitons in Bose-Einstein condensates (BECs) with the time-dependent interatomic interaction in an expulsive parabolic and complex potential. We also demonstrate that the lifetime of both a bright soliton and a dark soliton in BECs can be extended by reducing both the ratio of the axial oscillation frequency to radial oscillation frequency and the loss of atoms. It is interesting that a train of bright solitons may be excited with a strong enough background. An experimental protocol is further designed for observing this phenomenon.

I. INTRODUCTION

The Bose-Einstein condensates (BECs) at kT temperature can be described by the mean-field-theory–nonlinear Schrödinger (NLS) equation with a trap potential, i.e., the Gross-Pitaevskii (GP) equation. Recently, with the experimental observation and theoretical studies of BECs [1], there has been intense interest in the nonlinear excitations of ultracold atoms, such as dark solitons [2–7], bright solitons [8–10], vortices [11], and four-wave mixing [12]. Recent experiments have demonstrated that variation of the effective scattering length, even including its sign, can be achieved by utilizing the so-called Feshbach resonance [13–15]. It has been demonstrated that the variation of nonlinearity of the GP equation via Feshbach resonance provides a powerful tool for controlling the generation of bright and dark soliton trains starting from periodic waves [16].

At the mean-field level, the GP equation governs the evolution of the macroscopic wave function of BECs. In the physically important case of the cigar-shaped BECs, it is reasonable to reduce the GP equation into a one-dimensional nonlinear Schrödinger equation with time-dependent atomic scattering length in an expulsive parabolic and complex potential [17–22],

\[ i\frac{\partial \psi}{\partial t} = -\frac{\partial^2 \psi}{\partial x^2} + 2a(t)|\psi|^2\psi - \frac{\lambda}{2}x^2\psi + i\gamma\psi, \]

where the time \( t \) and coordinate \( x \) are measured in units \( 2/\omega_x \) and \( a_x, \) and \( a_x = \sqrt{\hbar/m\omega_x} \) is linear oscillator lengths in the transverse and cigar-axis directions, respectively, \( \omega_x \) is the radial oscillation frequency and \( \omega_x \) is the axial oscillation frequency, \( m \) is the atomic mass, \( |\lambda| = 2|\omega_0|/\omega_x \ll 1, \) \( a(t) \) is a scattering length of attractive interactions \( |a(t)| < 0 \) or repulsive interactions \( |a(t)| > 0 \) between atoms, and \( \gamma \) is a small parameter related to the feeding of condensate from the thermal cloud [23]. When \( a(t) = a_0 \exp(\lambda t) \) and \( \gamma = 0, \) Liang et al. present a family of exact solutions of Eq. (1) by Darboux transformation and analyze the dynamics of a bright soliton [17]. Kengne et al. investigated Eq. (1) with \( a(t) = a_0 \) and \( \gamma = \lambda/2 \) and verified the dynamics of a bright soliton proposed [18]. These results show that, under a safe range of parameters, the bright soliton can be compressed into very high local matter densities by increasing the absolute value of the atomic scattering length or feeding parameter.

In this paper, we develop a direct method to derive two families of exact solitons of Eq. (1), then give some thorough analysis for a bright soliton, a train of bright solitons, and a dark soliton. Our results show that for the BEC system with time-dependent atomic scattering length, the lifetime of a bright or a dark soliton in BECs can be extended by reducing both the ratio of the axial oscillation frequency to radial oscillation frequency and the loss of atoms. It is demonstrated that a train of bright solitons in BECs may be excited with a strong enough background. We also propose an experimental protocol to observe this phenomenon in further experiments.

II. THE METHOD AND SOLITON SOLUTIONS

We can assume the solutions of Eq. (1) as follows:

\[ \psi = \left(A_0(t) + A_1(t)\frac{\delta \cosh(\xi + \gamma \cosh \eta)}{\cosh(\xi + \gamma \cosh \eta)} + iB_1(t)\frac{\alpha \sinh(\eta) + \beta \sin \eta}{\cosh(\xi + \gamma \cosh \eta)}\right)\exp(i\Delta), \]

where \( \Delta = k_0(t) + k_1(t)x + k_2(t)x^2, \) \( \xi = p_1(t)x + q_1(t), \) \( \eta = p_3(t)x + q_2(t), A_0(t), A_1(t), B_1(t), p_1(t), q_1(t), p_2(t), q_2(t), k_0(t), k_1(t), \) and \( k_2(t) \) are real functions of \( t \) to be determined, and \( \alpha, \beta, \delta \) are real constants.

Substituting Eq. (2) into Eq. (1), we first remove the exponential terms, then collect coefficients of \( \sinh(\xi)\cosh(\xi)\sin^m(\eta)\cos^n(\eta) \) \( (i=0,1,2,...; \ j=0,1; \ m = 0,1,2,...; \ n = 0,1; \ k = 0,1,\ldots) \) and separate the real part and the imaginary part for each coefficient. We derive a set of ordinary differential equations (ODEs) with respect to \( a(t), A_0(t), A_1(t), B_1(t), p_1(t), q_1(t), p_2(t), q_2(t), k_0(t), k_1(t), \) and \( k_2(t) \). Finally, solving these ODEs, we can obtain two families of analytical solutions of Eq. (1).
Family 1. When interaction between atoms is attractive such as $^7$Li atoms, $a(t)<0$, the solution of Eq. (1) can be written as

$$\psi_1 = \Omega (A_e + A_s \text{sech}(\xi) \exp(i\Delta + \gamma t)), \tag{3}$$

where

$$\Delta = k_2(t)x^2 + k_1 \Omega^2 x + (2g_0 A_s^2 - k_1^2) \int \Omega^4 dt,$$

$$\xi = \sqrt{g_0 A_e \left[ \beta \Omega^2 x - 2 \left( k_1 + p_2 - \frac{2g_0^2 A_s^2}{(g_0 A_s^2 + p_2^2)} \right) \int \Omega^4 dt \right]},$$

$$\eta = p_2 \Omega^2 x - [2p_1 k_1 + (p_2^2 - g_0 A_s^2)\beta] \int \Omega^4 dt,$$

$$a(t) = -g_0 \Omega^2 \exp(-2\gamma t), \quad \alpha = -2 \sqrt{g_0 A_e A_s^2 / (g_0 A_s^2 + p_2^2)},$$

$$\beta^2 = [p_2^2 + g_0 (A_s^2 - 4A_e^2)] / (g_0 A_s^2 + p_2^2),$$

$$\delta = -2g_0 A_e A_s / (g_0 A_s^2 + p_2^2),$$

$$\Omega = \exp \left( -2k_2(t) \right), \quad k_2(t) = \left[ \pm \frac{\lambda - \lambda}{2} \tan(\lambda t) \right],$$

and $A_e, A_s, g_0 > 0, p_2, k_1, \gamma$ are arbitrary real constants.

Family 2. When interaction between atoms is repulsive such as $^{23}$Na and $^{87}$Rb atoms, $a(t)>0$, the solution of Eq. (1) can be written as

$$\psi_2 = \Omega [A_e + iA_s \tanh(\xi)] \exp(\Delta + \gamma t), \tag{4}$$

where

$$\xi = \pm \sqrt{g_0 A_e \Omega^2 x + 2A_s \sqrt{g_0 A_s + A_e}} \int \Omega^4 dt, \quad \Delta = k_2(t)x^2 + k_1 \Omega^2 x - [2g_0 (A_s^2 + k_1^2)] \int \Omega^4 dt,$$

$$a(t) = g_0 \Omega^2 \times \exp(-2\gamma t), \quad \Omega, k_2(t)$$

are the same as in Eq. (3); $A_e, A_s, g_0 > 0, k_1, \gamma$ are arbitrary real constants.

The solutions (3) and (4) are new general solutions of Eq. (1) that can describe the dynamics of bright and dark solitons in BECs with the time-dependent interatomic interaction in an expulsive parabolic and complex potential. In a special case, it can be reduced to solutions obtained by others. For example, if $k_2(t)=-\lambda/4$ and $\gamma=0$, the solution (3) describes the dynamics of a bright soliton in BECs with time-dependent atomic scattering length in an expulsive parabolic potential, and it can reduce the solution in Ref. [17]. If $k_2(t)=-\lambda/4$ and $\gamma=\lambda/2$, Eq. (3) describes the dynamics of bright matter wave solitons in BECs in an expulsive parabolic and complex potential, and it can recover the solution in Ref. [18].

To our knowledge, the other solutions from Eqs. (3) and (4) have not been reported earlier. When $k_2(t)=\pm \lambda/4$ and $\gamma$ is a fixed value, the intensities of Eqs. (3) and (4) are either exponentially increasing or exponentially decreasing so the BECs phenomenon cannot be stable reasonably. Thus in order to close the experimental condition and compare our theoretical prediction with experimental results, we will only discuss and analyze Eqs. (3) and (4) with $k_2(t) = \lambda/4 \tan(\lambda t)$ and $\Omega^2 = \text{sech}(\lambda t)/2$.

A. Dynamics of bright solitons in BECs

In the following, we are interested in two cases of Eq. (3).

Case (1) of Eq. (3)

When $\alpha=0$ and $p_2=0$, $\psi_1$ can be written as

$$\psi_{11} = \Omega (A_e + A_s \text{sech}(\xi) \exp(\Delta + \gamma t)), \tag{5}$$

where $A_s^2 > 4A_e^2$, and

$$\xi = \sqrt{g_0 A_e \Omega^2 x - 2 \sqrt{g_0 A_e} k_1} \int \Omega^4 dt,$$  

$$\eta = g_0 (A_e^2 - 4A_s^2)/\beta \int \Omega^4 dt, \quad \beta^2 = (A_e^2 - 4A_s^2)/A_s^2,$$  

$$\Delta = k_2(t)x^2 + k_1 \Omega^2 x + (2g_0 A_s^2 - k_1^2) \int \Omega^4 dt,$$  

$$\Omega = \sqrt{\text{sech}(\lambda t)/2}, \quad \delta = -2A_e/A_s,$$  

$$a(t) = -(g_0/2) \text{sech}(\lambda t) \exp(-2\gamma t).$$

When $A_e=0$, $\psi_{11}$ reduces to the background

$$\psi_e = A_s \Omega \exp(i\Delta + \gamma t). \tag{6}$$

When $A_e=0$, $\psi_{11}$ reduces to the bright soliton

$$\psi_j = A_s \Omega \text{sech}(\xi) \exp(i\Theta + \gamma t), \tag{7}$$

where

$$\xi = \sqrt{g_0 A_s \Omega^2 x - 2 \sqrt{g_0 A_s} (k_1 + p_2)} \int \Omega^4 dt,$$  

$$\Theta = k_2(t)x^2 + k_1 \Omega^2 x + (g_0 A_s^2 - k_1^2) \int \Omega^4 dt.$$

Thus $\psi_{11}$ represents a bright soliton embedded in the background. At the same time, when $A_e \ll A_s$ satisfies $4A_e^2 < A_s^2$ and $\gamma$ small, the background is small within the existence of a bright soliton.

Considering the dynamics of the bright soliton in the background, the length $2L$ of the spatial background must be very large compared to the scale of the soliton. In the real experiment [8], the length of the background of BECs can reach at least $2L=370 \mu m$. In Fig. 1, the width of the bright soliton is about $2L=14 nm$ [a unity of coordinate, $\Delta \approx 1$ in the dimensionless variables, corresponds to $a_\perp = (\hbar / (\omega_0) (1/2) \approx 1.4 \mu m$]. So $\theta \ll L$, a necessary condition for realizing bright soliton in experiment. From Fig. 1(a), under the realistic experiment parameters in [10], $\omega_\perp = 2\pi \times 710 Hz$ and $\omega_0=2\pi \times 70 Hz$. In order to cope with the experiment, the soliton moves to the $-x$ direction, $\lambda$
accordance with the experimental data of Ref.

bright solitons in BECs.

changing magnetic

bach resonance technology, the experimental physicists can

see that the lifetime of the BEC is about 20 \times 10^4 s = 9 ms, which is close to the experiment results: the

time of a BEC is about 8 ms. Here, by Eq. (9), we can

verify that the number of atoms in the bright soliton against

lifetime of a BEC is about 8 ms. Here, by Eq.

\[ \frac{\Delta t}{t_0} = -0.01, \]

\[ a(t) = -0.2 \text{ sech}(0.197t) \exp(0.1t) \]

which arrives at the order of the lifetime of a BEC in today's

dimensionless time corresponding to a real time of 0.1 s,

the parameter varies continually, and

they only measure a particular value of soliton corresponding

to the fixed magnetic field. When we fix the magnetic field at

a fixed value (the scattering length is also a fixed value) such as

\( B = 425 \text{ G} \) in Ref. [10], the scattering length is

\( a_s = -0.21 \text{ nm} \); then the special value of our general solution is in

accordance with the experimental data of Ref. [10].

Of course, we believe that with the development of the Fesh-

bach resonance technology, the experimental physicists can

measure the motion of solitons in the future. Thus by modu-

lating the scattering length in time via changing magnetic

field near the Feshbach resonance, we may also realize the

bright solitons in BECs.

When \( \lambda = -0.02 \) (which can be derived from \( \omega_0 = 2\pi \times 7 \text{ Hz} \) and \( \omega_1 = 2\pi \times 710 \text{ Hz} \) and \( \gamma = -0.99 \)), from Fig.

1(b), the lifetime of the BEC can reach about 200 unities of

the dimensionless time corresponding to a real time of 0.1 s, which

arrives at the order of the lifetime of a BEC in today's

experiments. Here, we can verify that when \( t \) is from \(-120 \) to

80, (i) the number of atoms is in the range of 4824 and 3234

by Eq. (9); (ii) the scattering length \( -0.20 \leq a(t) \leq -0.03 \text{ nm} \); and (iii) from Eq. (5), we can derive

\[ \xi = -1/2 \sqrt{g_0 / A_s - 4A_s^2(x - k_1 t - x_0)}, \]

therefore \( k_1 \) describes the ve-

locity of the bright soliton, which can be demonstrated by Fig. 1.

It is necessary to point out the following. (i) In order to
give clear figures, the parameter \( k_1 \) is taken to be relatively
small. In reality, \( k_1 \) is about \(-4 \), which can be derived from

the soliton's position \( x = -k_1 \exp(-\lambda t) / \lambda_1 \). (ii) The background

is very small with regard to the bright soliton in Fig. 1,

which can also be shown by Fig. 2. Therefore, the back-

ground may be taken as zero background approximately. (iii)
In order to keep the lifetime of the bright soliton about 8 ms, we take \( \gamma = -0.01 \), which may be the experimental value. When \( \gamma = -0.01 \), by varying the value of \( \lambda \), it is difficult to extend the lifetime of the bright soliton. Thus in order to extend the lifetime of a soliton in BEC, we should take appropriate measures to reduce the absolute value of \( \lambda \) and \( \gamma \), as is shown in Fig. 1(b).

Furthermore, we find that when \( \cosh(\xi) = -2A_c \cos(\eta)/A_1 + A_1/[A_c \cos(\eta)] \) [\( \sinh(\xi) = 0 \)], the intensity of Eq. (5) arrives at the minimum (maximum),

\[
|\psi_1|^2_{\lim} = A_1^2 \left( 1 - \frac{(A_1^2 - 4A_c^2) \cos^2(\eta)}{A_1^2 - 4A_c^2 \cos^2(\eta)} \right) \frac{\text{sech}(\lambda t)}{2} e^{2\gamma t},
\]

\[
|\psi_1|^2_{\lim} = A_1^2 \left( \frac{A_1^2}{A_1^2 - 4A_c^2 \cos^2(\eta)} \right) \frac{\text{sech}(\lambda t)}{2} e^{2\gamma t}.
\]

This means that the bright solitons (5) can only be squeezed into the assumed peak matter density between the minimum and maximum values. Figure 2 present the evolution plots of the maximal and minimal intensities given by \( |\psi_1|^2_{\lim} \) (blue line) and \( |\psi_1|^2_{\lim} \) (yellow line) and the background intensity (red line) with different parameters. From Fig. 2, with the time evolution, first the intensities increase until the peak, then they decrease to the background. Meanwhile, the smaller \(|\lambda|\) and \(|\gamma|\), the longer the higher intensities can remain. Therefore, in order to keep a bright soliton in BECs for a longer time, we should reduce both the ratio of the axial oscillation frequency to the radial oscillation frequency and the loss of atoms.

To investigate the stability of the bright soliton in the expulsive parabolic and complex potential, we obtain

\[
\int_{-L}^{+L} (|\psi_1|^2 - |\psi_2|^2) dx = N_0 C_L,
\]

where

\[
N_0 = (2 \sqrt{A_1^2 - 4A_c^2/\gamma_0}) \exp(2\gamma t),
\]

\[
C_L = A_1 \{\exp(2L) - 1\}/\{A_1 [\exp(2L) + 1] - 4A_c \cos(\eta) \exp(L)\},
\]

which is the exact number of atoms in the bright soliton against the background described by Eq. (5) within \([-L, L]\). This indicates that when \( L \) takes a fixed value, for example \( L = 100 \), then \( C_L = 1 \), therefore the number of atoms in the bright soliton is determined by \( N_0 \).

In contrast, the quantity

\[
\int_{-L}^{+L} |\psi_{11} - \psi_2|^2 dx = N_0 (C_L + 4A_c M \cos(\eta)),
\]

where \( N_0 \) and \( C_i \) are determined by Eqs. (10) and (11), and

\[
M = \frac{1}{\Theta} \arctan \left( \frac{A_1 + 2A_c \cos(\eta) \exp(L) - 1}{\Theta \exp(L) + 1} \right),
\]

counts the number of atoms in both the bright soliton and background under the condition of \( \psi(\pm L, t) \neq 0 \). Equation (12) displays that a time-periodic atomic exchange is formed between the bright soliton and the background. In the case of zero background, i.e., \( A_1 = 0 \), from Eq. (12) the exchange of atoms depends on the sign of \( \gamma \): (i) when \( \gamma = 0 \), there will be no exchange of atoms; (ii) when \( \gamma < 0 \), the exchange of atoms decreases; (iii) when \( \gamma > 0 \), the exchange of atoms increases. As shown in Fig. 3, in the case of nonzero background and \( \gamma < 0 \), a slow-fast-slow process of atomic exchange is performed between the bright soliton and the background, but the whole trend of the atomic exchange between the bright soliton and the background decreases. In Ref. 24, Wu et al. show that the number of atoms continuously injected into Bose-Einstein condensate from the reservoir depends on the linear gain or loss coefficient, and cannot be controlled by applying the external magnetic field via Feshbach resonance. The findings here can yield the same results.

In addition, under the integration constant of \( \int \Omega^2(t) dt \) taken to be zero, Eq. (5) takes the following particular form at \( t_0 = \frac{1}{2\pi} \ln \left( \frac{\exp(A_1^2 - 4A_c^2)}{\lambda/\exp(4A_1^2)} \right) \) \( k = 0, \pm 1, \pm 2, \ldots \):

\[
\psi_{11} = \Omega(t_0) [\pm A_{1i} \pm iA_{1i} \beta \sech(\xi) \exp(i\Delta + \gamma t_0)].
\]

This means that Eq. (13) can be generated by coherently adding a bright soliton into the background.

Inspired by two experiments [8, 10], we can design an experimental protocol to control the soliton in BECs near Feshbach resonance with the following steps: (i) Create a bright soliton in BECs with the parameters of \( N = 4 \times 10^3 \), \( \omega_1 = 2\pi \times 700 \text{ Hz} \), and \( \omega_0 = 2\pi \times 7 \text{ Hz} \) and for \( ^7 \text{Li} \). (ii) Under the safe range of parameters discussed above, ramp up the absolute value of the scattering length according to \( a(t) \)
SOLITONS IN BOSE-EINSTEIN CONDENSATES ...

\[ \psi_{12} = \Omega \left( A_x + A_s \frac{\delta \cosh(\xi) + \cos(\eta) + i \alpha \sinh(\xi)}{\cosh(\xi) + \cos(\eta)} \right) \times \exp(i\Delta + \gamma t), \] (14)

where \(4A_x^2 - \lambda > 0\) and

\[ \xi = \sqrt{g_0 A_x p_2} \int \Omega^2 dt, \quad \alpha = -p_2 / (2\sqrt{g_0 A_x}), \]

\[ \eta = p_2 \Omega^2 x - 2p_2 k_1 \int \Omega^4 dt, \quad \delta = -A_x / (2A_s), \]

\[ p_2 = g_0 (4A_x^2 - \lambda^2), \quad \Omega = \sqrt{\text{sech}(\lambda t)/2}. \]

Analysis reveals that \(\psi_{12}\) is periodic with a period \(\Gamma = 4\pi / [p_2 \text{sech}(\lambda t)]\) in the space coordinate \(x\) and aperiodic in the temporal variable \(t\). Note that the period \(\Gamma\) is not a constant due to the presence of the function \(\text{sech}(\lambda t)\), but when \(\lambda \ll 1\) and \(t\) is very small, \(\Gamma\) is very close to \(4\pi / p_2\). As shown in Fig. 4, when \(\lambda = -0.197, A_x = 7, A_s = 12, g_0 = 0.4, k_1 = -0.01, \) and \(\gamma = -0.01\). (b) is the contour plot.

\[ \frac{g_0}{2} \text{sech}(\lambda t) \exp(-2\gamma t) \] due to Feshbach resonance, control the dispersion of atoms in BECs at a low level by modulating the parameter \(\gamma\) about to \(-0.001\), and take \(\lambda\) to be a very small value: \(\lambda = -2(\omega_0)/\omega_1 = -0.02\). A unity of time, \(\Delta t = 1\) in the dimensionless variables, corresponds to real seconds \(2/\omega_1 = 4.5 \times 10^{-4}\). (iii) During 200 dimensionless units of time, the absolute value of the atomic scattering length varies in \(0.03 \leq |a(t)| \leq 0.20\) nm. This means that during the process of the bright soliton, the stability of the soliton and the validity of the 1D approximation can be kept as displayed in Fig. 1(b). Therefore, the phenomena discussed in this paper should be observable within the current experimental capability.

Case (II) of Eq. (3)

When \(\beta = 0\), the solution \(\psi_{12}\) is written as

\[ \psi_{12} = \Omega \left( A_x + A_s \frac{\delta \cosh(\xi) + \cos(\eta) + i \alpha \sinh(\xi)}{\cosh(\xi) + \cos(\eta)} \right) \times \exp(i\Delta + \gamma t). \]

Therefore, the solution (4) should be a time-dependent dark soliton, which can be shown by Fig. 5. From Eq. (4), we can obtain the intensities of the background as follows:

\[ |\psi_1|^2 = (A_x^2 + A_s^2)[\text{sech}(\lambda t)/2] \exp(2\gamma t). \] (16)

Therefore from Eq. (16), we guess that the solution (4) may describe an interesting physical process: there is a “moving stop,” which may be realized by use of a laser, at both ends of the cigar-axis direction.

Proceeding as in the case of the bright soliton, we obtain

\[ \int_{-\infty}^{\infty} |\psi_{12}|^2 - |\psi_{12}(\pm \infty, t)|^2 dx = - (2A_s^2 / \sqrt{g_0}) \exp(2\gamma t). \] (17)

which describes the region of decreased density and contains a negative “number of atoms.”

As shown in Fig. 5, when the absolute values of \(\lambda\) and \(\gamma\) are smaller, the dark solitons can remain for a longer time and propagate a longer distance. Under the conditions in Fig. 5, the scattering lengths are in a range \(0.05 \leq |a(t)| \leq 0.20\) nm. Therefore, in order to keep a dark soliton for a long time in BECs, we should also reduce the values of \(\lambda\) by

\[ \gamma = -0.01, \] a train of bright solitons is excited. Here the atoms in a bright soliton and in the background in a period \([0, \Gamma]\) are \(\int_0^\Gamma |\psi_{12}|^2 dx = 3510, \int_0^\Gamma |A_x\Omega|^2 dx = 6815\), respectively. Thus we can conclude that an important condition for exciting a train of bright solitons is that the background is strong enough.

B. Dynamics of a dark soliton in BECs

When \(\lambda \rightarrow 0\) and \(\gamma \rightarrow 0\), Eq. (4) is reduced to the dark soliton [25],

\[ \psi_2 = (\sqrt{2}/2)[A_x + iA_s \tanh((\sqrt{g_0}/2)[x + A_x(k_1 + \sqrt{g_0}A_x)])] \times \exp(i\Delta). \] (15)

FIG. 4. (Color online) The evolution plots of \(|\psi_{12}|^2\) with \(\lambda = -0.197, A_x = 7, A_s = 12, g_0 = 0.4, k_1 = -0.01, \) and \(\gamma = -0.01\). (b) is the contour plot.

FIG. 5. (Color online) The evolution contour plots of \(|\psi_{12}|^2\), where \(A_x = 7, A_s = 12, g_0 = 0.4, k_1 = -4.4, \lambda = -0.197, \) and \(\gamma = -0.01\) in (a); \(\lambda = -0.02\) and \(\gamma = -0.001\) in (b).
adjacent the harmonic-oscillator frequencies $\omega_x$ and $\omega_y$ and reduce the absolute value of $\gamma$ by controlling the loss of atoms.

### III. CONCLUSIONS

In summary, we present a direct method to obtain two families of analytical solutions for the nonlinear Schrödinger equation which describe the dynamics of solitons in Bose-Einstein condensates with the time-dependent interatomic interaction in an expulsive parabolic and complex potential. The dynamics of a bright soliton, a train of bright solitons, and a dark soliton are analyzed thoroughly. We can extend the lifetime of a bright soliton or a dark soliton in BEC by reducing the ratio of the axial oscillation frequency to radial oscillation frequency and control the loss of atoms. Meanwhile, our results also demonstrate that a train of bright solitons in BEC may be excited with a strong enough background. It will be very interesting to find these new phenomena, which are of special importance in the field of an atom laser, in further experiments.

### ACKNOWLEDGMENTS

B.L. would like to express his sincere thanks to Professor G. X. Huang and Professor Z. D. Li for their helpful discussions. This work is supported by the NSF of China under Grants No. 10747141, No. 10735030, No. 90406017, No. 60525417, No. 10740420252, the NKBRSF of China under Grants No. 2005CB724508 and No. 2006CB921400, Zhejiang Provincial NSF of China under Grant No. 605408, Ningbo NSF under Grants No. 2007A610049 and No. 2006A610093, and K.C. Wong Magna Fund in Ningbo University.
